| 2011 | • | [ <b>Boito2011a</b> ]: Include DV model to extract $\alpha_s$ from OPAL data.   |
| 2018 | • | [ <b>Boito2018</b> ]: $\alpha_s$ from $e^+e^- \rightarrow$ hadrons up to 2 GeV.   |

The strong coupling has been measured since many years from hadronic  $\tau$  decays. Until today most of the applied QCDSR to  $\tau$  decays are based on the methodology developed in the early nineties by Braaten, Pich and Narison [**Braaten1991**]. They gathered the at this time available perturbative and NP contributions to extract the strong coupling from comparing their theoretical results to the known inclusive hadronic  $\tau$  decay ratio  $R_\tau$ . Pich together with Le Diberger then formulated the fitting strategy of fitting multiple moments of different weights to extract  $\alpha_s$  parallel to Wilson coefficients of the OPE [**LeDiberger1992**], which later has been applied as standard in the ALEPH [**Aleph1993**] as well

as the OPAL [**Opal1998**] detectors. For the next ten year years the methodology of extracting the strong coupling did not run through make major changes until in the year 2011 when Boito, Cata, Golterman, Jamin, Osborn and Peris [**Boito2011a**] applied a duality model to include known DV effects to the QCD analysis of  $\tau$  decays. The group around Boito and Pich have different opin-

ions on the importance of the newly introduced duality model [Pich2016, Boito2016] and consequently we want to deliver a third, opinion on the subject, favouring fits without the duality model. With new data becoming available from  $e^+e^-$  annihilation the extraction of  $\alpha_s$  has recently been extended to analyses up to 2 GeV [Boito2018].

## 1.1 Fit Strategy

The objective of this work is to extract  $s$  and argue about the importance of  $DV$ . Apart from the two main objectives we want to analyse the values of the OPE Wilson coefficients of up to dimension ten.

Our fitting strategy will be in choosing weights of lower and higher pinching. Lower pinched weights should be affected by  $DV$ , while higher pinched weights should be protected from  $DV$ . As a result in comparing different fits of lower and higher pinched weights it should be possible to argue about strength of the  $DV$  that are (or are not) present.

Our hypothesis is that  $DV$  are tiny for fits of the combined vector and axial-vector channel in combination with pinched weights. Consequently we can extract parameters, like the strong coupling  $\alpha_s$  from  $\tau$  decays to high precision without a  $DV$  model.

We will perform our analysis in the framework of FOPT, but display our final results also in CIPT. Consequently to define a fit we have to choose a weight  $\omega$  and a momentum  $s_0$ . The only restriction from choosing a weight is, that the weight has to be analytic, leaving us with a variety of choices. For our strategy we have chosen three categories of weights, each of them containing fits with three different weights. A table with an overview of all used weights is given in [table 1.2](#) To test for the stability of the fitted values and have enough DOF to fit the higher OPE contributions we furthermore fit every weight for various momenta  $s_0$ .

|            | Symbol                    | Term            | Expansion                  | OPE Contributions |
|------------|---------------------------|-----------------|----------------------------|-------------------|
| Pinched    | $\omega_\tau$             | $(1-x)^2(1+2x)$ | $1-3x^2+2x^3$              | D6, D8            |
|            | $\omega_{\text{cube}}$    | $(1-x)^3(1+3x)$ | $1-6x^2+8x^3-3x^4$         | D6, D8, D10       |
|            | $\omega_{\text{quartic}}$ | $(1-x)^4(1+3x)$ | $1-10x^2+20x^3-15x^4+4x^5$ | D6, D8, D10, D12  |
| Monomial   | $\omega_{M2}$             | $1-x^2$         | $1-x^2$                    | D6                |
|            | $\omega_{M3}$             | $1-x^3$         | $1-x^3$                    | D8                |
|            | $\omega_{M4}$             | $1-x^4$         | $1-x^4$                    | D10               |
| Pinched +x | $\omega_{X2}$             | $(1-x)^2$       | $1-2x+x^2$                 | D4, D6            |
|            | $\omega_{X3}$             | $(1-x)^3$       | $1-3x+3x^2-x^3$            | D4, D6, D8        |
|            | $\omega_{X4}$             | $(1-x)^4$       | $1-4x+6x^2-4x^3+x^4$       | D4, D6, D8, D10   |

Table 1.2: Displaying three categories of fits, each containing three weights with their corresponding mathematical expression and the OPE contributions the fitted integral momentum will be sensitive to.

## 1.2 Fits

In the following we will give the results of each of the three previously mentioned fit categories.

The first category contains the *Pinched Weights without Monomial  $x$* . The chosen weights are double ( $\omega_\tau$ ), triple ( $\omega_{\text{cube}}$ ) and quadruple ( $\omega_{\text{quartic}}$ ) pinched and do not contain a monomial term  $x$ . An  $x$  term would make the fits sensitive to the  $D = 4$  OPE contribution and have a unreliable perturbative expansion [Beneke2012]. The higher the pinching, the higher the suppression of  $DV$ . Consequently if we obtain stable values for  $\alpha_s$  from the different pinched fits we should expect the  $DV$  to have no influence on the value of the strong coupling. The different weights imply an increasing number of active OPE contributions  $D_6, D_8, D_{10}$  and  $D_{12}$ , which can be used to compare to the stability of higher order OPE contributions and to test for the convergence of the OPE.

The second category contains the *Single Pinched Monomial weights*. In this case all of the weights are only single pinched and, as in the first category, do not carry a monomial in  $x$ . Consequently if  $DV$  affect the fits we should notice different fitting results in comparison to the fits of the first category. Furthermore the single pinched moments only carry two parameters, the strong coupling

and an OPE Wilson coefficients. Thus we can further compare the  $C_6, C_8$  and  $C_{10}$  Wilson coefficients and argue about the stability of the fits.

The third and last category contains a similar pinching to the as compared to the first category, but this time contains a monomial term in  $x$ . Consequently these fits are unreliable in the framework of FOPT and we have to apply the *Borel sum* (BS). Following the logic of the second and first category we then can compare the result to analyse the role of DV compare the Wilson coefficients.

### 1.2.1 Pinched Weights without Monomial $x$

$$\text{Kinematic weight: } \omega_\tau(x) \equiv (1-x)^2(1+2x)$$

We have already encountered the kinematic weight in ???. It is a polynomial weight function, defined as  $\omega_\tau(x) = (1-x)^2(1+2x)$ , double pinched, contains the unity and does not contain a term proportional to  $x$ . Consequently it is an optimal weight [Beneke2012]. As a doubled pinched weight it should have a good suppression of DV contributions and its polynomial contains terms proportional to  $x^2$  and  $x^3$ , which makes it sensitive to the dimension six and eight OPE contributions. The fits have been performed within the framework of FOPT for different numbers of  $s_0$ . The momentum sets are characterised by its lowest energy  $s_{\min}$ . We fitted values down to 1.5 GeV. Going to lower energies is questionable due to the coupling constant becoming to large, which implies a breakdown of PT and appearing DVs. Furthermore it bares the risk to be affected by the  $\rho(770)$  and  $a_1$  peaks in the vector and axial-vector spectral function, which we cannot model within the framework of the OPE. For the fitting-parameters  $\alpha_s, C_6$  and  $C_8$  we have given the results in table 1.3 and graphically in fig. 1.1. We only display the fits for  $s_{\min}$  larger than 2.1 GeV as fits with higher  $s_{\min}$  have either a too large  $\chi^2$  (larger than two) or have been excluded by us because the  $\chi^2$  value jumps from 0.19 to 1.3 between the  $s_{\min} = 2.1$  and  $s_{\min}=2.2$  fits. We experienced this behaviour with various of our fits, which will be discussed later. Consequently we achieved achieved four good fits with a  $\chi^2$  per DOF less or close to one, which we divided into two groups:

- Fits with 5-7 momenta have  $\chi^2$  per DOF larger than one and means of

| $s_{\min}$ | $\#s_0s$ | $\alpha_s(m_\tau^2)$ | $c_6$     | $c_8$     | $\chi^2/\text{dof}$ |
|------------|----------|----------------------|-----------|-----------|---------------------|
| 2.100      | 8        | 0.3256(38)           | -0.43(15) | -0.25(28) | 1.30                |
| 2.200      | 7        | 0.3308(44)           | -0.72(20) | -0.85(38) | 0.19                |
| 2.300      | 6        | 0.3304(52)           | -0.69(25) | -0.80(50) | 0.25                |
| 2.400      | 5        | 0.3339(70)           | -0.91(39) | -1.29(83) | 0.10                |
| 2.600      | 4        | 0.3398(15)           | -1.3(1.0) | -2.3(2.5) | 0.01                |

Table 1.3: Table of our fitting values of  $\alpha_s(m_\tau^2)$ ,  $c_6$  and  $c_8$  for the kinematic weight  $\omega(x) = (1-x)^2(1+2x)$  using FOPT ordered by increasing  $s_{\min}$ . The errors are given in parenthesis after the observed value.

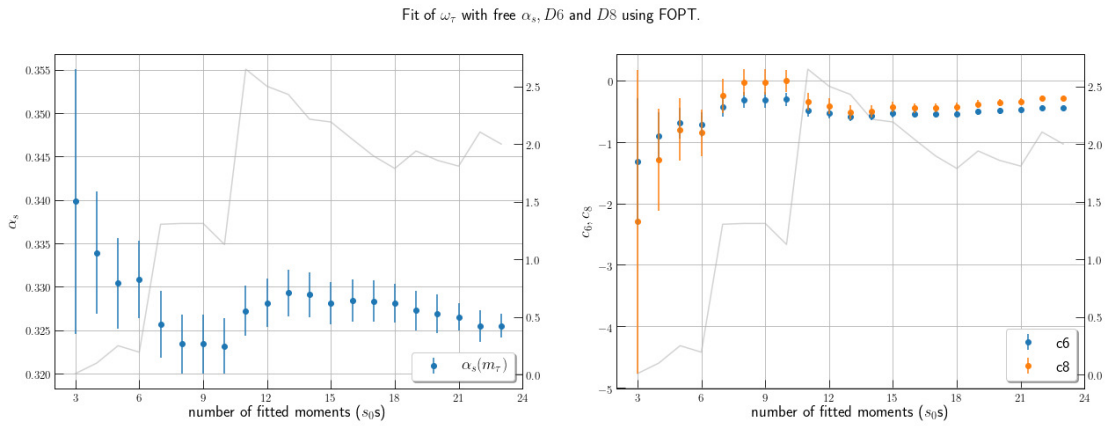

Figure 1.1: Fitting values of  $\alpha_s(m_\tau^2)$ ,  $c_6$  and  $c_8$  for the kinematic weight  $\omega(x) = (1-x)^2(1+2x)$  using FOPT for different  $s_{\min}$ . The left graph plots  $\alpha_s(m_\tau^2)$  for different numbers of used  $s_0s$ . The right plot contains the dimension six and eight contributions to the OPE. Both plots have in grey the  $\chi^2$  per DOF.

Figure 1.2: test

$\alpha(m_\tau^2) = 0.3317(33)$ ,  $c_6 = -0.77(17)$  and  $c_8 = -0.98(35)$ , where we propagated the uncertainty. We have excluded the momentum containing four  $s_0s$ , because it  $\chi^2$  is too low and its errors are too large, which is because we have to fix three variables for only four data points.

- Fits with **8-10** momenta have small  $\chi^2$  per DOF values and lower means for the strong coupling  $\alpha(m_\tau^2) = 0.3241(20)$  but the OPE contributions are higher  $c_6 = -0.350(75)$  and  $c_8 = -0.09(12)$ .

The values for the less momenta are preferred by us due to two reasons. First below energies of 2.2 GeV we have to face the problematic influence of increasing resonances. Second, we will see, that the values obtained from the lower moment fits are more compatible with our other fits series. For both, the momenta sets, we see a good convergence of the OPE.

We further tested the stability of the dimension six and eight contributions to the OPE within the same fit series but for a fixed value of the strong coupling to our previous averaged result  $\alpha_s(m_\tau^2) = 0.3179$ . The fits have been plotted

Figure 1.3

in [fig. 1.3](#) and show good stability. The values for  $c_6$  and  $c_8$  are larger than the values given in our final results from [table 1.3](#). This is explained with a smaller contribution from the strong coupling ( $\alpha_s$  is smaller), which has to be compensated by larger OPE contributions.

Due to the good results we will try to argue in favour of the values obtained by the lower momenta:

$$\alpha_s(m_\tau^2) = 0.3317(33), \quad c_6 = -0.77(17) \quad \text{and} \quad c_8 = -0.98(35). \quad (1.2.1)$$

### 1.2.2 Cubic weight: $\omega_{\text{cube}}(x) \equiv (1-x)^3(1+3x)$

To further consolidate the results from the kinematic weight, we test a weight of higher pinching, which is known to suppress DV more than a double pinched weight would do. Consequently, any differences to the previous fit could indicate a problem with the DV treatment. Our *cubic* weight will be triple pinched and optimal, as the kinematic weight is double pinched and we do not want any problematic contributions proportional to  $x$ . Thus we define the *cubic weight* as  $\omega_{\text{cube}}(x) \equiv (1-x)^3(1+3x)$ . It is due to its polynomial structure sensitive to the dimensions six, eight and ten contributions of the OPE, which yields one more parameter to fit than with the kinematic weight  $\omega_\tau$ . The some good, selected fits, by  $\chi^2$  per DOF, can be seen in [table 1.4](#) and graphically in [section 1.2.2](#). As with the kinematic weight we get two different sets of value:

- The fits with **9, 10 and 11** momenta have a too high  $\chi^2$ , but are comparable to our the upper entries of the kinematic weight [table 1.3](#). As

| $s_{\min}$ | $\#s_0s$ | $\alpha_s(m_\tau^2)$ | $c_6$      | $c_8$      | $c_{10}$  | $\chi^2/\text{dof}$ |
|------------|----------|----------------------|------------|------------|-----------|---------------------|
| 1.900      | 11       | 0.3249(29)           | -0.280(20) | -0.088(21) | 0.088(55) | 1.58                |
| 1.950      | 10       | 0.3237(26)           | -0.232(25) | 0.005(42)  | 0.275(93) | 1.67                |
| 2.000      | 9        | 0.3228(26)           | -0.196(27) | 0.075(28)  | 0.420(56) | 1.96                |
| 2.100      | 8        | 0.3302(40)           | -0.52(11)  | -0.58(22)  | -1.00(45) | 0.43                |
| 2.200      | 7        | 0.3312(43)           | -0.56(12)  | -0.68(23)  | -1.23(50) | 0.55                |
| 2.300      | 6        | 0.336(11)            | -0.78(47)  | -1.17(98)  | -2.38(22) | 0.29                |
| 2.400      | 5        | 0.3330(96)           | -0.63(47)  | -0.82(10)  | -1.51(26) | 0.48                |

Table 1.4: Table of our fitting values of  $\alpha_s(m_\tau^2)$ ,  $c_6$ ,  $c_8$  and  $c_{10}$  for the cubic weight  $\omega(x) = (1-x)^3(1+3x)$  using FOPT ordered by increasing  $s_{\min}$ . The errors are given in parenthesis after the observed value.

with the kinematic weight the  $s_{\min}$  seems to be affected by lower resonances.

- The fits with **5,6,7 and 8** have a better  $\chi^2$  per DOF value and are in good agreement with the corresponding fits of the kinematic weight. The averaged value with its propagated errors read:  $\alpha_s(m_\tau^2) = 0.332478(61)$ ,  $c_6 = -0.622(12)$ ,  $c_8 = -0.815(55)$  and  $c_{10} = -1.5(3.1)$ .

We furthermore found that the OPE is converging, but not as good as for the kinematic weight. The values of  $|\delta^{(8)}|$  is only half as large as  $|\delta^{(8)}|$ . The values of the lower momentum count are in high agreement with the ones obtained from the kinematic weight. The conclusions that we take from the *cubic weight* are that the kinematic weight, with its double pinching, should sufficiently suppress any contributions from DVs. If DV would have an effect on the kinematic weight, we should have seen an improvement of the fits with the *cubic weight*, due to its triple pinching, which is not the case.

### 1.2.3 Quartic weight: $\omega(x) \equiv (1-x)^4(1+4x)$

To include an even higher pinching of four and to compare the previously obtained value for the dimension ten OPE contribution we performed fits with the *quartic weight* defined as  $\omega(x) \equiv (1-x)^4(1+4x)$ , which also fulfils the definition of an optimal weight [Beneke2012]. Unfortunately the fits only converged for  $s_{\min} = 2 \text{ GeV}$  (nine  $s_0$ s moment combination). The results for , with a  $\chi^2$  per DOF of 0.67 are given by:

$$\begin{aligned} \alpha_s(m_\tau^2) = 0.3290(11), \quad c_6 = -0.3030(46), \quad c_8 = -0.1874(28), \\ c_{10} = 0.3678(45) \quad \text{and} \quad c_{12} = -0.4071(77) \end{aligned} \tag{1.2.2}$$

Due to the problematic of the fitting routing, which is caused by too many OPE contributions fitted simultaneously, we will discard the fitting results for the quartic weight.

### 1.2.4 Single Pinched Monomial Weights

$$1 - x^2$$

$$1 - x^3$$

$$1 - x^4$$

### 1.2.5 Pinched Weights with monomial $x$

$$(1 - x)^2$$

$$(1 - x)^3$$

$$(1 - x)^4$$

## 1.3 Results

In the following we will perform fits to determine  $\alpha_s$  at the  $m_\tau^2$ -scale. The fits are separated corresponding to the used weight. Every weight contains multiple fits for different  $s_0$ -momenta. We will start with the kinematic weight, which appears naturally in the inclusive  $\tau$ -decay ratio ?? and has the best fitting characteristics of all weights we have used.

### 1.3.1 Third power monomial: $\omega_{m3}(x) \equiv 1 - x^3$

To study the behaviour of the DV and the higher order OPE contributions of dimension eight and ten we further included two optimal, single pinched weights. The first one is defined as  $\omega_{m3}(x) \equiv 1 - x^3$  and contains a single third power monomial and is consequently sensitive to dimension eight contributions from the OPE. Our fitting results can be taken from [table 1.5](#). The  $\chi^2$  per DOF is like in the  $\omega_\tau$  and  $\omega_{\text{cubic}}$  fits good for  $s_{\min} \leq 2.2 \text{ GeV}$ , but jumps to values  $\chi^2/\text{dof} > 1.4$  for smaller  $s_{\min}$ . This is, as before, explained through resonances that appear in lower energies. Due to the good  $\chi^2$  and the internally compatible fitting values we averaged over all rows except the last one of [table 1.5](#). The last row, at  $s_{\min} = 2.8 \text{ GeV}$  has only one DOF and thus high

| $s_{\min}$ | $\#s_0s$ | $\alpha_s(m_\tau^2)$ | $c_8$       | $\chi^2/\text{dof}$ |
|------------|----------|----------------------|-------------|---------------------|
| 2.200      | 7        | 0.3214(49)           | -1.01(39)   | 0.41                |
| 2.300      | 6        | 0.3227(57)           | -1.18(54)   | 0.46                |
| 2.400      | 5        | 0.3257(67)           | -1.58(74)   | 0.39                |
| 2.600      | 4        | 0.325(10)            | -1.54(1.53) | 0.58                |
| 2.800      | 3        | 0.326(21)            | -1.69(4.03) | 1.17                |

Table 1.5: Table of our fitting values of  $\alpha_s(m_\tau^2)$ , and  $c_8$  for the single pinched third power monomial weight  $\omega(x) = 1 - x^3$  using FOPT ordered by increasing  $s_{\min}$ . The errors are given in parenthesis after the observed value.

errors. The averaged values are thus given by

$$\alpha(m_\tau^2) = 0.32382(42) \quad \text{and} \quad c_8 = -1.33(67). \quad (1.3.1)$$

We note that the strong coupling is smaller as our expected values from the kinematic weight ??, but the dimension eight contribution is in good agreement. The strong coupling from the monomial weight to third order seems to be in better agreement with the 8-10 momenta used in the kinematic fits, whereas the dimension eight contributions agrees more with the 4-7 momenta fits.

We have made use of a single pinched weight and discovered that the fitting result is not completely compatible with our previous fitting results. Consequently weights with a pinching less than two are affected by DV and should not be used to determine the strong coupling.

### 1.3.2 Fourth power monomial: $\omega_{m4}(x) \equiv 1 - x^4$

We already analysed the cubic and quartic weights, which depend on the dimension ten OPE contribution, in [section 1.2.2](#) and [section 1.2.3](#) correspondingly. Now, even with the visible DV for fourth power monomial  $\omega_{m4} \equiv 1 - x^4$  to study another single pinched moment and the dimension ten OPE contribution. The results of the are given in ??. The fitting behaviour is very similar to

| $s_{\min}$ | $\#s_0s$ | $\alpha_s(m_\tau^2)$ | $c_{10}$     | $\chi^2/\text{dof}$ |
|------------|----------|----------------------|--------------|---------------------|
| 2.200      | 7        | 0.3203(48)           | -1.64(77)    | 0.42                |
| 2.300      | 6        | 0.3216(56)           | -2.01(1.13)  | 0.47                |
| 2.400      | 5        | 0.3247(66)           | -2.98(1.62)  | 0.39                |
| 2.600      | 4        | 0.324(10)            | -2.86(3.69)  | 0.58                |
| 2.800      | 3        | 0.325(20)            | -3.43(10.74) | 1.17                |

Table 1.6: Table of our fitting values of  $\alpha_s(m_\tau^2)$  and  $c_{10}$  for the single pinched fourth power monomial weight  $\omega(x)=1-x^4$  using FOPT ordered by increasing  $s_{\min}$ . The errors are given in parenthesis after the observed value.

the third power monomial (??) and we will directly cite our obtained results:

$$\alpha_s(m_\tau^2) = 0.32277(40) \quad \text{and} \quad c_{10} = -2.4(3.6). \quad (1.3.2)$$

As before the values for the strong coupling are lower than the ones obtained by the kinematic weight fit. Furthermore the error on the tenth dimension contribution of the OPE are too huge, although the huge errors makes it compatible with all previous results. All in all the usage of the single pinched fourth power monomial weight is questionable and does not deliver any additional insights.

### 1.3.3 Pich's Optimal Moments [Pich2016]

Next to the previously mentioned *optimal weights* from Beneke and Jamin [Beneke2012] there are *optimal moments* introduced by Pich [LeDiberder1992]. Combinations of these optimal moments have been widely used by the ALEPH collaboration to perform QCD analysis on the Large electron-positron collider (LEP). These moments include the for FOPT problematic proportional term in  $x$  [Beneke2012], thus we will perform additional fits in the Borel-sum.

$$\omega_{(n,m)}(x) = (1-x)^n \sum_{k=0}^m (k+1)x^k \quad (1.3.3)$$

$$\omega(\mathbf{x}) = (\mathbf{1}-\mathbf{x})^2$$

| $s_{\min}$ | $\#s_0s$ | $\alpha_s(m_\tau^2)$ | aGGInv      | $c_6$     | $\chi^2/\text{dof}$ |
|------------|----------|----------------------|-------------|-----------|---------------------|
| 2.200      | 7        | 0.3401(57)           | -0.0185(52) | 0.220(88) | 0.73                |
| 2.300      | 6        | 0.3383(68)           | -0.0165(67) | 0.26(12)  | 0.89                |
| 2.400      | 5        | 0.3450(93)           | -0.0243(99) | 0.10(17)  | 0.71                |
| 2.600      | 4        | 0.337(16)            | -0.014(18)  | 0.36(45)  | 0.98                |

Table 1.7: Table of our fitting values of  $\alpha_s(m_\tau^2)$ , aGGInv and  $c_6$  for the triple pinched optimal weight  $\omega^{(2,0)}(\mathbf{x}) = (1 - \mathbf{x})^2$  using FOPT ordered by increasing  $s_{\min}$ . The errors are given in parenthesis after the observed value.

$$\omega(\mathbf{x}) = (\mathbf{1}-\mathbf{x})^3$$

| $s_{\min}$ | $\#s_0s$ | $\alpha_s(m_\tau^2)$ | aGGInv       | $c_6$      | $c_8$      | $\chi^2/\text{dof}$ |

Table 1.9: Table of the best fits (selected by  $\chi^2/\text{dof}$  and compatibility of the fitting values) for each weight including at least the strong coupling  $\alpha_s(m_\tau^2)$  as a fitting variable. All fits have been performed using `FORT`, except weights marked with a star  $\omega^*$ , which have been fitted using the *Borel sum*.

### 1.3.4 Comparison

To create an overview of our previous results we have gathered the most compatible rows by hand. These are shown in [table 1.9](#), which is composed of two parts:

- The upper three rows represent fits we found to have good properties for determining the strong coupling.
- The lower five rows are problematic fits due to too many OPE contributions, too low pinching or to terms proportional to  $x$ .

We have found that the kinematic weight is in excellent agreement with the cubic  $\omega_{\text{cube}}$  and Pich's optimal weight  $\omega_{3,0}$ , fitted using the borel model. The fitted parameters from the kinematic weight ( $\alpha_s$ ,  $c_6$  and  $c_8$ ) are all within error ranges and thus compatible. One fact that has to be investigated is the negative appearing sign for the gluon-condensate from the borel-sum of  $\omega_{3,0}$ .
