

# Chapter 1

## Introduction

In particle physics we are concerned about small objects and their interactions. Their dynamics are currently best described by the Standard Model (SM).

The SM contains two groups of fermionic, Spin 1/2 particles. The former group, the Leptons consist of: the electron ( $e$ ), the muon ( $\mu$ ), the tau ( $\tau$ ) and their corresponding neutrinos  $\nu_e$ ,  $\nu_\mu$  and  $\nu_\tau$ . The latter group, the Quarks contain:  $u$ ,  $d$  (up and down, the so called light quarks),  $s$  (strange),  $c$  (charm),  $b$  (beauty or beauty) and  $t$  (top or truth). The SM furthermore differentiates between three fundamental forces (and its carriers): the electromagnetic ( $\gamma$  photon), weak (Z- or W-Boson) and strong ( $g$  gluon) interactions. The before mentioned Leptons solely interact through the electromagnetic and the weak force (also referred to as electroweak interaction), whereas the quarks additionally interact through the strong force.

The strong force is denominated Quantumchromodynamics (QCD). As the name suggest<sup>1</sup> the force is characterized by the color charge. Every quark has next to its type one of the three colors blue, red or green. The color force is mediated through eight gluons, which each being bi-colored<sup>2</sup>, interact with quarks and each other. The strength of the strong force is given by the coupling constant  $\alpha_s$ . The coupling constants are a function of energy  $E$  and  $\alpha_s(E)$  increases with energy<sup>3</sup>. This is exclusive for QCD and leads to *asymptotic freedom* and *confinement*. The former phenomenon describes the decreasing strong force between quarks and gluons, which become asymptotically free at large energies. The latter expresses the fact, that no isolated quark has been found until today. Quarks appear confined as *Hadrons*, the so called *Mesons*<sup>4</sup> and *Baryons*<sup>5</sup>. As we measure *Hadrons* in our experiments but calculate with quarks within our theoretical QCD model we have to assume *Quark-Hadron Duality*, which states that QCD is still valid for Hadrons for energies suffi-

---

<sup>1</sup>Chromo is the greek word for color.

<sup>2</sup>Each gluon carries a color and an anti-color.

<sup>3</sup>In contrast to the electromagnetic force, where  $\alpha(E)$  decreases!

<sup>4</sup>Composite of a quark and an anti-quark.

<sup>5</sup>Composite of three quarks or three anti-quarks.

cently high energies. There exist *Duality Violations* (DV), which will be investigated within this work.

In the following (section 1.1) we will describe the  $\tau$ -decays, which play an essential role in our QCD analysis. Then (section 1.2) we want to explain some more details of QCD, especially about the coupling constant  $\alpha_s(s)$  (which is not constant at all) and the *QCD sum rules*.

## 1.1 $\tau$ -Decays

The  $\tau$ -particle is an elementary particle with negative electric charge and a spin of  $1/2$ . Together with the lighter electron and muon it forms the *charged Leptons*<sup>6</sup>. Even though it is an elementary particle it decays via the *weak interaction* with a lifetime of  $\tau_\tau = 2.9 \times 10^{-13} \text{ s}$  and a mass of  $1776.86(12) \text{ MeV}$ [13]. It is the only lepton massive enough to decay into Hadrons. The final states of a decay are limited by *conservation laws*. In case of a  $\tau$ -decay they must conserve the electric charge ( $-1$ ) and *invariant mass* of the system. Thus, as we can see from the corresponding Feynman diagram (see section 1.1)<sup>7</sup> the  $\tau$  decays by the emission of a  $W$  boson and a tau-neutrino  $\nu_\tau$  into different pairs of  $(e^-, \bar{\nu}_e)$ ,  $(\mu^-, \bar{\nu}_\mu)$  or  $(q, \bar{q})$ .

Figure 1.1: Feynman diagram of common decay of a  $\tau$ -lepton into pairs of lepton-antineutrino or quark-antiquark by the emission of a  $W$  boson.

We are foremost interested into the hadronic decay channels, meaning  $\tau$ -decays that have quarks in their final states. Unfortunately the quarks have never been measured isolated, but appear always in combination of *mesons* and *baryons*. Due to its mass of  $m_\tau \approx 1.8 \text{ GeV}$  the  $\tau$ -particle decays into light mesons (pions- $\pi$ , kaons-K, and eta- $\eta$ , see section 1.1), which can be experimentally detected.

The hadronic  $\tau$  – decay provides one of the most precise ways to determine the strong coupling [10] and can be calculated to high precision within the framework of QCD.

<sup>6</sup>Leptons do not interact via the strong force.

<sup>7</sup>The  $\tau$ -particle can also decay into strange quarks or charm quarks, but these decays are rather uncommon due to the heavy masses of  $s$  and  $c$ .

Name	Symbol	Quark content	Rest mass (MeV)
Pion	$\pi^-$	$\bar{u}d$	139.570 61(24) MeV
Pion	$\pi^0$	$(u\bar{u} - d\bar{d})/\sqrt{2}$	134.9770(5) MeV
Kaon	$K^-$	$\bar{u}s$	493.677(16) MeV
Kaon	$K^0$	$d\bar{s}$	497.611(13) MeV
Eta	$\eta$	$(u\bar{u} + d\bar{d} - 2s\bar{s})/\sqrt{6}$	547.862(17) MeV

Table 1.1: List of mesons produced by a  $\tau$ -decay. Rare final states with branching Ratios smaller than 0.1 have been omitted. The list is taken from [4] with corresponding rest masses taken from [13].

Flavour	Mass	comment
u	$2.2^{+0.5}_{-0.4}$ MeV	$\overline{MS}$
d	$4.7^{+0.5}_{-0.3}$ MeV	
s	$95^{+9}_{-3}$ MeV	
c	$1.275^{+0.025}_{-0.035}$ GeV	
b	$4.18^{+0.04}_{-0.03}$ GeV	
t	173.0(40) GeV	

Table 1.2: List of Quarks and their masses[13].

## 1.2 Quantumchromodynamics

QCD describes the strong interaction, which occur between *quarks* and are transmitted through *gluons*. A list of quarks can be found in 1.2.

The QCD Lagrange density is similar to that of QED[5],

$$\mathcal{L}_{\text{QCD}}(x) = -\frac{1}{4}G_{\mu\nu}^a(x)G^{\mu\nu a}(x) + \sum_A \left[ \frac{i}{2}\bar{q}^A(x)\gamma^\mu \overleftrightarrow{D}_\mu q^A(x) - m_A \bar{q}^A(x)q^A(x) \right], \quad (1.1)$$

where  $q^A(x)$  represents the quark fields and  $G_{\mu\nu}^a$  being the *gluon field strength tensor* given by:

$$G_{\mu\nu}^a(x) \equiv \partial_\mu B_\nu^a(x) - \partial_\nu B_\mu^a(x) + gf^{abc}B_\mu^b(x)B_\nu^c(x), \quad (1.2)$$

where  $B_\mu^a$  are the *gluon fields*, given in the *adjoint representation* of the SU(3) gauge group with  $f^{abc}$  as *structure constants*. Furthermore we have used  $A, B, \dots = 0, \dots, 5$  as flavour indices,  $a, b, \dots = 0, \dots, 8$  as color indices and  $\mu, \nu, \dots = 0, \dots, 3$  as lorentz indices.

### 1.2.1 Renormalisation Group

The perurbations of the QCD Lagrangian 1.1 lead to divergencies, which have to be *renormalized*. There are different approaches to ‘make’ these divergencies

finite. The most popular one is *dimensional regularisation*. In *Dimensional regularisation* we expand the four space-time dimensions to arbitrary dimensions. Consequently the in QCD calculations appearing *Feynman integrals* have to be continued to D-dimensions like

$$\mu^{2\epsilon} \int \frac{d^D p}{(2\pi)^D} \frac{1}{[p^2 - m^2 + i0][(q - p)^2 - m^2 + i0]}, \quad (1.3)$$

where we introduced the scale parameter  $\mu$  to account for the extra dimensions and conserve the mass dimension of the non continued integral.

In addition *physical quantities*<sup>8</sup> cannot depend on the renormalisation scale  $\mu$ . Thus examining a *physical quantity*  $R(q, a_s, m)$  that depends on the external momentum  $q$ , the renormalised coupling  $a_s = \alpha_s/\pi$  and the renormalized quark mass  $m$

$$\mu \frac{d}{d\mu} R(q, a_s, m) = \left[ \mu \frac{\partial}{\partial \mu} + \mu \frac{da_s}{d\mu} \frac{\partial}{\partial a_s} + \mu \frac{dm}{d\mu} \frac{\partial}{\partial m} \right] R(q, a_s, m) = 0 \quad (1.4)$$

we can define the *renormalisation group functions*:

$$\beta(a_s) \equiv -\mu \frac{da_s}{d\mu} = \beta_1 a_s^2 + \beta_2 a_s^3 + \dots \quad \beta - \text{function} \quad (1.5)$$

$$\gamma(a_s) \equiv -\frac{\mu}{m} \frac{dm}{d\mu} = \gamma_1 a_s + \gamma_2 a_s^2 + \dots \quad \text{anomalous mass dimension.} \quad (1.6)$$

### Running gauge coupling

Regarding the  $\beta$ -function we notice, that  $a_s(\mu)$  is not a constant, but *runs* by varying the scale  $\mu$ . Integrating the  $\beta$ -function yields

$$\int_{a_s(\mu_1)}^{a_s(\mu_2)} \frac{da_s}{\beta(a_s)} = - \int_{\mu_1}^{\mu_2} \frac{d\mu}{\mu} = \log \frac{\mu_1}{\mu_2}. \quad (1.7)$$

To analytically evaluate the above integral we can approximate the  $\beta$ -function to first order, with the known coefficient

$$\beta_1 = \frac{1}{6}(11N_c - 2N_f), \quad (1.8)$$

yielding

$$a_s(\mu_2) = \frac{a_s(\mu_1)}{\left(1 - a_s(\mu_1)\beta_1 \log \frac{\mu_1}{\mu_2}\right)}. \quad (1.9)$$

As we have three colours  $N_c = 3$  and six flavours  $N_f = 6$  the first  $\beta$ -function 1.5 is positive. Thus for  $\mu_2 > \mu_1$   $a_s(\mu_2)$  decreases logarithmically and vanishes for  $\mu_2 \rightarrow \infty$ . This behaviour is known as *asymptotic freedom*. The coefficients of the  $\beta$ -function are currently known up to the 5th order, which are displayed in the appendix 4.1.

---

<sup>8</sup>Observables that can be measured.

### Running quark mass

The properties of the running quark mass can be derived similar to the gauge coupling. Starting from integrating the *anomalous mass dimension* 1.6

$$\log \frac{m(\mu_2)}{m(\mu_1)} = \int_{a_s(\mu_1)}^{a_s(\mu_2)} da_s \frac{\gamma(a_s)}{\beta(a_s)} \quad (1.10)$$

we can approximate the *anomalous mass dimension* to first order and solve the integral analytically [11]

$$m(\mu_2) = m(\mu_1) \left( \frac{a(\mu_2)}{a(\mu_1)} \right)^{\frac{\gamma_1}{\beta_1}} (1 + \mathcal{O}(\beta_2, \gamma_2)). \quad (1.11)$$

As  $\beta_1$  and  $\gamma_1$  (see 4.2) are positive the quark mass decreases with increasing  $\mu$ . The general relation between different scales is given by

$$m(\mu_2) = m(\mu_1) \exp \left( \int_{a_s(\mu_1)}^{a_s(\mu_2)} da_s \frac{\gamma(a_s)}{\beta(a_s)} \right) \quad (1.12)$$

and can be solved numerically to run the quark mass to the needed scale  $\mu_2$ .

### 1.2.2 Sum Rules

We need to relate the measurable hadronic final states of a QCD process (e.g.  $\tau$ -decays into Hadrons) to a theoretical calculable value. Consequently we will employ **QCD Sum Rules**[12], which is a combination of the **operator product expansion** (OPE), the **optical theorem**, a **dispersion relation** the analyticity of the **two-point function** and the **quark hadron duality**.

Starting from the the vacuum expectation value of the product of the conserved noether current  $J_\mu(x)$  at different space-times points  $x$  and  $y$ , which is known as the *two-point function* (or simply correlator)

$$\Pi(q^2) = \langle 0 | J_\mu(x) J_\nu(y) | 0 \rangle, \quad (1.13)$$

where the noether current is given by

$$J_\mu(x) = \Psi^\dagger(x) \gamma_\mu (\gamma_5) \Psi(x). \quad (1.14)$$

The two-point function, within the framework of QCD sum rules, is improved by the OPE expansion

$$\Pi_{\text{OPE}}(s) = \sum_n C_{2n}(s, \mu) \frac{\langle \hat{\mathcal{O}}(\mu) \rangle}{s^n}, \quad (1.15)$$

where we used  $q^2 = s$ . It is furthermore related to the hadronic **spectral function**  $\rho(q^2)$  through the *Källén-Lehmann spectral representation* [6][8]

$$\Pi(q^2) = \int_0^\infty ds \frac{\rho(s)}{s - q^2 - i\epsilon}, \quad (1.16)$$

where the spectral function  $\rho(s)$  is defined as

$$\rho(s) \equiv \frac{1}{\pi} \text{Im} \Pi(s). \quad (1.17)$$

Equation 1.16 is referred to as **dispersion relation** analogous to similar relations which arise for example in electrodynamics. The main contribution from the spectral function given in eq. (1.16) are the hadronic final states

$$2\pi\rho(m^2) = \sum_n \langle 0 | J_\mu(x) | n \rangle \langle n | J_\nu(y) \rangle (2\pi^2)^4 \delta^{(4)}(p - p_n), \quad (1.18)$$

which lead to a series of continuous poles on the positive real axis for the two-point function, see Fig. 1.2.2. As the experimental data, which solely

Figure 1.2: Analytic structure in the complex  $q^2$ -plane of the Fourier transform of the two-point function. The hadronic final states are responsible for poles appearing on the real-axis. The one-particle states contribute as isolated pole and the multi-particle states contribute as bound-states poles or a continuous “discontinuity cut” (see [9]).

contributes to the spectral function  $\rho(q^2)$ , is only accessible on the positive real axis, we have to use Cauchy’s theorem to access the theoretical values of the two-point function close to the positive real axis (see section 1.2.2).

The final ingredient of the QCD sum rules is the *optical theorem*, relating experimental data with the imaginary part of the correlator. E.g. taking the total  $e^+e^-$  cross section scattering into hadrons

$$R_q(s) \equiv \frac{\sigma(e^+e^- \rightarrow \gamma^* \rightarrow q\bar{q})}{\sigma(e^+e^- \rightarrow \mu^+\mu^-)} = 12\pi \text{Im} \Pi_{\text{Had}}(s). \quad (1.19)$$

Figure 1.3: Analytical structure of  $\Pi(s)$  with the used contour  $\mathcal{C}$  for the final QCD Sum Rule expression [eq. \(1.20\)](#).

Due to asymptotic freedom<sup>9</sup> experiments can only detect Hadrons (note the exp-index in  $\text{Im}\Pi_{\text{exp}}(s)$ ), but on the theory side we are calculating with quarks as degrees of freedom. Consequently we assume that  $\Pi_{\text{Had}}$  can be set equal to  $\Pi_{\text{OPE}}$ , which is referred to as *quark hadron duality*.

In total, with the help Cauchy's theorem, the QCD sum rules can be summed up in the following expression

$$\frac{1}{\pi} \int_0^\infty \frac{\text{Im} \Pi_{\text{Had}}(t)}{t-s} dt = \frac{1}{\pi} \oint_{\mathcal{C}} \frac{\text{Im} \Pi_{\text{OPE}}(t)}{t-s} dt, \quad (1.20)$$

where the l.h.s. is given by the experiment and the r.h.s. can be theoretically evaluated with by applying the OPE of the correlator  $\Pi_{\text{OPE}}(s)$ .

---

<sup>9</sup>There are no free quarks. They are bound in pairs of two or three.

## Chapter 2

### $\tau$ decays into hadrons

$$R_\tau = \frac{\Gamma(\tau \rightarrow \nu_\tau + \text{Hadrons})}{\Gamma(\tau \rightarrow \nu_\tau e^+ e^-)} \quad (2.1)$$

in terms of V/A, S/P [3]

$$\begin{aligned} \Pi^{\mu\nu}(q^2) &= (q^\mu q^\nu - q^2 g^{\mu\nu}) \Pi^{V,A}(q^2) + \frac{g^{\mu\nu}}{q^2} (m_i \mp m_j) \Pi^{S,P}(q^2) \\ &\quad + g^{\mu\nu} \frac{(m_i \mp m_j)}{q^2} [\langle \bar{q}_i q_i \rangle \mp \langle \bar{q}_j q_j \rangle] \end{aligned} \quad (2.2)$$

$$q_\mu q_\nu \Pi^{\mu\nu}(q^2) = (m_i \mp m_j)^2 \Pi^{S,P}(q^2) + (m_i \mp m_j) [\langle \bar{q}_i q_i \rangle \mp \langle \bar{q}_j q_j \rangle] \quad (2.3)$$

in terms of T and L

$$(q^\mu q^\nu - g^{\mu\nu} q^2) \Pi^{(T)}(q^2) + q^\mu q^\nu \Pi^{(L)}(q^2) \quad (2.4)$$

$$q_\mu q_\nu \Pi^{\mu\nu}(q^2) = q^4 \Pi^{(L)}(q^2) = s^2 \Pi^{(L)}(s), \quad (2.5)$$

where  $s \equiv q^2$

relation L and S,P

$$s^2 \Pi^{(L)}(s) = (m_i \mp m_j)^2 \Pi^{(S,P)}(s) + (m_i \mp m_j) [\langle \bar{q}_i q_i \rangle \mp \langle \bar{q}_j q_j \rangle] \quad (2.6)$$

need relation T and V,A

$$\begin{aligned} \Pi^{\mu\nu}(s) &= \underbrace{(q^\mu q^\nu - g^{\mu\nu} q^2) \Pi^{(T)}(s) + (q^\mu q^\nu - g^{\mu\nu} q^2) \Pi^{(L)}(s)}_{=(q^\mu q^\nu - g^{\mu\nu} q^2) \Pi^{(T+L)}(s)} + \frac{g^{\mu\nu} s^2}{q^2} \Pi^{(L)}(s) \end{aligned} \quad (2.7)$$

where  $\Pi^{(T+L)}(s) \equiv \Pi^{(T)}(s) + \Pi^{(L)}(s)$

$$\Pi^{(V,A)}(s) = \Pi^{(T)}(s) + \Pi^{(L)}(s) = \Pi^{(T+L)}(s) \quad (2.8)$$

$$q_\mu q_n u \quad (2.9)$$

The theoretical expression of the hadronic  $\tau$ -decay ratio was first derived by [14] (using current algebra, a more recent derivation making use of the \*optical theorem\* can be taken from [11]):

$$R_\tau = 12\pi \int_0^{m_\tau} \frac{ds}{m_\tau^2} \left(1 - \frac{s}{m_\tau^2}\right) \left[ \left(1 + 2\frac{s}{m_\tau^2}\right) \text{Im } \Pi^{(T)}(s) + \text{Im } \Pi^{(L)} \right]. \quad (2.10)$$

$R_\tau$  introduces a problematic integral over the real axis of  $\Pi(s)$  from 0 up to  $m_\tau$ . The integral is problematic for two reasons:

- The *perturbative Quantum Chromodynamics* (**pQCD**) and the OPE breaks down for low energies (over which we have to integrate).
- The positive euclidean axis of  $\Pi(s)$  has a discontinuity cut and can theoretically not be evaluated.

To literally circumvent these issues we make use of *Cauchy's Theorem*

$$\int_{\mathcal{C}} f(z) dz = 0, \quad (2.11)$$

where  $f(z)$  is an analytic function on a closed contour  $\mathcal{C}$ .

In our case we have to deal with the two-point correlator  $\Pi(s)$ , which is analytic except for the positive real axis (with which we will deal with to a later point<sup>1</sup>) Consequently, to rewrite we can rewrite the definite integral of eq. (2.10) into a contour integral over a closed circle with radius  $m_\tau^2$ . The closed contour consists of four line integrals, which have been visualized in fig. 2.1. Summing over the four line integrals, performing a *analytic continuation* of the two-point correlator  $\Pi(s) \rightarrow \Pi(s + i\epsilon)$  and finally taking the limit of  $\epsilon \rightarrow 0$  gives us the needed relation between eq. (2.10) and the closed contour:

$$\begin{aligned} \oint_{s=m_\tau} \Pi(s) &= \int_0^{m_\tau} \Pi(s + i\epsilon) ds + \int_{\mathcal{C}_2} \Pi(s) ds + \int_{m_\tau}^0 \Pi(s - i\epsilon) ds + \int_{\mathcal{C}_4} \Pi(s) ds \\ &= \int_0^{m_\tau} \Pi(s + i\epsilon) - \Pi(s - i\epsilon) ds + \int_{\mathcal{C}_2} \Pi(s) ds + \int_{\mathcal{C}_4} \Pi(s) ds \\ &= \int_0^{m_\tau} \Pi(s + i\epsilon) - \overline{\Pi(s + i\epsilon)} + \int_{\mathcal{C}_2} \Pi(s) ds + \int_{\mathcal{C}_4} \Pi(s) ds \\ &\stackrel{\lim \epsilon \rightarrow 0}{=} 2i \int_0^{m_\tau} \text{Im } \Pi(s) ds + \oint_{s=m_\tau} \Pi(s) ds \end{aligned} \quad (2.12)$$

where we made use of  $\Pi(z) = \overline{\Pi(\bar{z})}$  (due to  $\Pi(s)$  is analytic) and  $\Pi(z) - \overline{\Pi(\bar{z})} = 2i \text{Im } \Pi(z)$ . The result can be rewritten in a more intuitive form, which we also

<sup>1</sup>To not evaluate  $\Pi(s)$  at the positive real axis we have to introduce *pinched weights*. The *pinched weights* vanish for  $s \rightarrow m_\tau$ .

Figure 2.1: Visualization of the usage of Cauchy's theorem to transform eq. (2.10) into a closed contour integral over a circle of radius  $m_\tau$ .

visualized in fig. 2.1

$$\int_0^{m_\tau} \Pi(s) ds = \frac{i}{2} \oint_{|s|=m_\tau} \Pi(s) ds \quad (2.13)$$

Finally combining eq. (2.13) with eq. (2.10) we get

$$R_\tau = 6\pi i \oint_{|s|=m_\tau} \frac{ds}{m_\tau^2} \left(1 - \frac{s}{m_\tau^2}\right) \left[ \left(1 + 2\frac{s}{m_\tau^2}\right) \Pi^{(T)}(s) + \Pi^{(L)} \right] \quad (2.14)$$

for the hadronic  $\tau$ -decay ratio.

The contour integral obtained is an import result as we can now theoretically evaluate the hadronic  $\tau$ -decay ratio sufficiently large energy scales ( $m_\tau \approx 1.78 \text{ MeV}$ ) at which  $\alpha_s(m_\tau) \approx 0.33$  [10] is tolerable heigh for applying perturbation theory and the OPE. Obviously we would benefit from a contour integral over a bigger circumference, but  $\tau$ -decays are limited by the  $m_\tau$ . Nevertheless there are promising  $e^+e^-$  annihilation data, which yields valuable R-ratio values up to 2 GeV [2][7].

It is convenient to rewrite the

$$\Pi^{(L+T)} = \Pi^{(L)} + \Pi^{(T)} \quad (2.15)$$

$$R_\tau = 6\pi i \oint_{|s|=m_\tau} \frac{ds}{m_\tau^2} \left(1 - \frac{s}{m_\tau^2}\right)^2 \left[ \left(1 + 2\frac{s}{m_\tau^2}\right) \Pi^{(L+T)}(s) - \left(\frac{2s}{m_\tau^2}\right) \Pi^{(L)}(s) \right] \quad (2.16)$$

$$D^{(L+T)}(s) \equiv -s \frac{d}{ds} \Pi^{(L+T)}(s), \quad D^{(L)}(s) \equiv \frac{s}{m_\tau^2} \frac{d}{ds} (s \Pi^{(L)}(s)) \quad (2.17)$$

Integration by parts

$$\int_a^b u(x)V(x) dx = [u(x)V(x)]_a^b - \int_a^b u(x)v(x) dx \quad (2.18)$$

$$\begin{aligned} R_\tau^{(1)} &= \frac{6\pi i}{m_\tau^2} \oint_{|s|=m_\tau^2} \underbrace{\left(1 - \frac{s}{m_\tau^2}\right)^2}_{=u(x)} \underbrace{\left(1 + 2\frac{s}{m_\tau^2}\right)}_{=V(x)} \Pi^{(L+T)}(s) \\ &= \frac{6\pi i}{m_\tau^2} \left\{ \left[ -\frac{m_\tau^2}{2} \left(1 - \frac{s}{m_\tau^2}\right)^3 \left(1 + \frac{s}{m_\tau^2}\right) \Pi^{(L+T)}(s) \right]_{|s|=m_\tau^2} \right. \\ &\quad \left. + \oint_{|s|=m_\tau^2} \underbrace{-\frac{m_\tau^2}{2} \left(1 - \frac{s}{m_\tau^2}\right)^3}_{=u(x)} \underbrace{\left(1 + \frac{s}{m_\tau^2}\right) \frac{d}{ds} \Pi^{(L+T)}(s)}_{=v(x)} \right\} \\ &= -3\pi i \oint_{|s|=m_\tau^2} \frac{ds}{s} \left(1 - \frac{s}{m_\tau^2}\right)^3 \left(1 + \frac{s}{m_\tau^2}\right) \frac{d}{ds} D^{(L+T)} \end{aligned} \quad (2.19)$$

where we fixed the integration constant to  $C = -\frac{m_\tau^2}{2}$  in the second line and left the antiderivatives contained in the squared brackets untouched. Parametrizing the expression in the squared brackets

$$\left[ -\frac{m_\tau^2}{2} (1 - e^{-i\phi})^3 (1 + e^{-i\phi}) \Pi^{(L+T)}(m_\tau^2 e^{-i\phi}) \right]_0^{2\pi} = 0 \quad (2.20)$$

where  $s \rightarrow m_\tau^2 e^{-i\phi}$  and  $(1 - e^{-i \cdot 0}) = (1 - e^{-i \cdot 2\pi}) = 0$ .

$$\begin{aligned} R_\tau^{(2)} &= \oint_{|s|=m_\tau^2} ds \left(1 - \frac{s}{m_\tau^2}\right)^2 \left(-\frac{2s}{m_\tau^2}\right) \Pi^{(L)}(s) \\ &= -4\pi i \oint \frac{ds}{s} \left(1 - \frac{s}{m_\tau^2}\right)^3 D^{(L)}(s) \end{aligned} \quad (2.21)$$

$$R_\tau = -\pi i \oint_{|s|=m_\tau^2} \frac{d}{ds} \left(1 - \frac{s}{m_\tau^2}\right)^3 \left[ 3 \left(1 + \frac{s}{m_\tau^2}\right) D^{(L+T)}(s) + 4 D^{(L)}(s) \right] \quad (2.22)$$

$$R_\tau = -\pi i \oint_{|s|=m_\tau^2} \frac{d}{dx} (1-x)^3 \left( 3(1+x) D^{(L+T)}(s) + 4 D^{(L)}(s) \right), \quad (2.23)$$

where  $x = s/m_\tau^2$ .

## Chapter 3

# Derivation of the used inverse covariance matrix from the Aleph data

While performing a **Generalized least squares** (GLS) we estimate our regression coefficients  $\hat{\beta}$  as follows:

$$\hat{\beta} = \underset{\mathbf{b}}{\operatorname{argmin}} (\mathbf{y} - \mathbf{X}\mathbf{b})^T \mathbf{\Omega}^{-1} (\mathbf{y} - \mathbf{X}\mathbf{b}), \quad (3.1)$$

with  $\mathbf{b}$  being an candidate estimate of  $\beta$ ,  $\mathbf{X}$  being the design matrix,  $\mathbf{y}$  being the response values and  $\mathbf{\Omega}^{-1}$  being the **inverse covariance matrix**.

The Aleph data includes the **standard error** (SE), which are equal to the **standard deviation** as per definition. Furthermore Aleph provides the **correlation coefficients** of the errors. We will use these two quantities in combination with **Gaussian error propagation** to derive an approximation of the covariance matrix.

### 3.1 Propagation of experimental errors and correlation

Let  $\{f_k(x_1, x_2, \dots, x_n)\}$  be a set of  $m$  functions, which are linear combinations of  $n$  variables  $x_1, x_2, \dots, x_n$  with combination coefficients  $A_{k1}, A_{k2}, \dots, A_{kn}$ , where  $k \in \{1, 2, \dots, m\}$ . Let the covariance matrix of  $x_n$  be denoted by

$$\Sigma^x = \begin{pmatrix} \sigma_1^2 & \sigma_{12} & \sigma_{13} & \cdots \\ \sigma_{12} & \sigma_2^2 & \sigma_{23} & \cdots \\ \sigma_{13} & \sigma_{23} & \sigma_3^2 & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix}. \quad (3.2)$$

Then the covariance matrix of the functions  $\Sigma^f$  is given by

$$\Sigma_{ij}^f = \sum_k^n \sum_l^n A_{ik} \sum_{kl}^x A_{jl}, \quad \Sigma^f = A \Sigma^x A^T. \quad (3.3)$$

In our case we are dealing with non-linear functions, which we will linearized with the help of the **Taylor expansion**

$$f_k \approx f_k^0 + \sum_i^n \frac{\partial f_k}{\partial x_i} x_i, \quad f \approx f^0 + Jx. \quad (3.4)$$

Therefore, the propagation of error follows from the linear case, replacing the Jacobian matrix with the combination coefficients ( $J = A$ )

## Chapter 4

# Coefficients

### 4.1 $\beta$ function

There are several conventions for defining the  $\beta$  coefficients, depending on a minus sign and/or a factor of two (if one substitutes  $\mu \rightarrow \mu^2$ ) in the  $\beta$ -function [1.5](#). We follow the convention from Pascual and Tarrach (except for the minus sign) and have taken the values from [\[1\]](#)

$$\beta_1 = \frac{1}{6}(11N_c - 2N_f) \quad (4.1)$$

$$\beta_2 = \frac{1}{12}(17N_c^2 - 5N_c N_f - 3C_f N_f) \quad (4.2)$$

$$\beta_3 = \frac{1}{32} \left( \frac{2857}{54} N_c^3 - \frac{1415}{54} N_c^2 N_f + \frac{79}{54} N_c N_f^2 - \frac{205}{18} N_c C_f N_f + \frac{11}{9} C_f N_f^2 + C_f^2 N_f \right) \quad (4.3)$$

$$\beta_4 = \frac{140599}{2304} + \frac{445}{16} \zeta_3, \quad (4.4)$$

where we used  $N_f = 6$  and  $N_c = 3$  for  $\beta_4$ .

### 4.2 Anomalous mass dimension

### 4.3 Adler function
